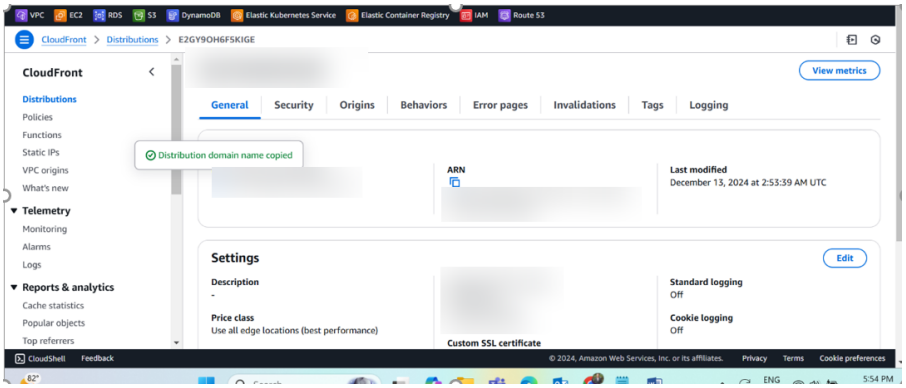
Setup of a sub domain console.astra.in and routing it to the main production EO application

Requirement: The client requested the creation of a subdomain, `console.astra.in`, to serve as the entry point for their EO Production Application. This subdomain should point to the CloudFront distribution, which has an S3 bucket (configured for static web hosting) as its origin.

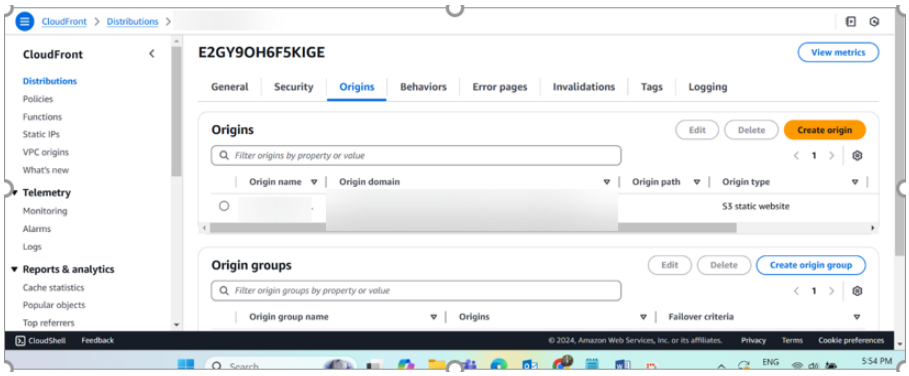
Objective: Create and configure the subdomain `console.astra.in` in Route 53 and link it to the EO Production Application hosted via CloudFront.

Steps Taken:

1. **Analyzed Requirements:**
   - Verified the client's request and confirmed that the EO Production Application is hosted in an S3 bucket, accessed via a CloudFront distribution.



Origin is set to s3.



2. **Configured Route 53 DNS Records:**
   - Added an **A Record** with the following details:
     - **Record Name:** console.astra.in
     - **Record Type:** A
     - **Value:** `87.cloudfront.net.`

        - Configured the value to point to the CloudFront distribution.
3. **Verified CloudFront Setup:**
    - Checked the configuration of the CloudFront distribution to ensure the origin is correctly set to the S3 bucket hosting the EO Production Application.
    - Verified the CloudFront settings, including caching policies and SSL/TLS configuration, to ensure secure and optimal performance.
4. **Validated Subdomain Functionality:**
    - Waited for DNS propagation to complete.
    - Accessed `console.astra.in` to confirm it resolves to the CloudFront distribution and serves content from the S3 bucket.
5. **Tested End-to-End Functionality:**
    - Performed thorough testing of the EO Production Application via `console.astra.in` to ensure seamless access and proper functionality.

Outcome: The subdomain `console.astra.in` was successfully created and linked to the EO Production Application. It now serves as the entry point for production and is fully functional.
